

Linear, as in Figure 1D

Display-enhanced

KIF13A

black 0, white 4095, $\gamma = 1.0$, not inverted

black 0, white 2537, $\gamma = 0.4529$, inverted

NUMA1

black 0, white 4095, $\gamma = 1.0$, not inverted

black 0, white 2032, $\gamma = 0.5463$, inverted

SYNE1

black 0, white 2118, $\gamma = 1.0$, not inverted

black 0, white 808, $\gamma = 0.6660$, inverted

Uncropped source images for Figure 1D. Exposure 0.09 s (KIF13A), 0.10 s (NUMA1), 0.10 s (SYNE1); 1392 × 1040 px, 12-bit. Left: complete gels, linear (black point 0, $\gamma = 1$, not inverted), same display parameters as the corresponding strips in Figure 1D; red outline marks the region shown there. Right: same data with the display transform stored in the .scn file (inverted), so that wells, gel edges and faint background are visible; this non-linear adjustment was applied globally and serves display only. Quantification used the unmodified 12-bit data. No pixel was saturated (maxima 3843 / 3589 / 2118 of 4095).
